A cover automaton of a finite language L is a finite automaton that accepts all words in L and possibly other words that are longer than any word in L. An algorithm for constructing a minimal cover automaton of a finite language L is given in a recent paper. This paper goes a step further by proposing a procedure for constructing all minimal cover automata of a given finite language L. The concept of cover automaton is then generalized to a form of extended finite automaton, the stream X-machine, and the procedure is extended to this more general model.

1. INTRODUCTION

Finite automata [1, 2, 3] are widely used in of computing, ranging from lexical analysis protocol testing. Finite automata are know regular languages [4, 5]. However, in many a finite automata only finite languages are used. states of a finite automaton (FA) that accept is at least one more than the length of the language and may be exponentially large On the other hand, if we do not restrict accept only the given finite language but extra words that are longer than the lo language, then the number of its states m reduced. In most applications the maxis words in the language is known and the sys of the length of the words processed, so will usually be adequate. This is the automata for finite languages.

Informally, a cover automaton of a finite language L is an FA that accepts all words in L and possibly other words that are longer than any word in L. A minimal cover automaton of L is a cover automaton of L having the least number of states. In many cases, a minimal cover automaton of L has a much smaller size than the minimal automaton that accepts L.

The concept of minimal cover automaton of a finite language is introduced in [6] and it is shown that there may be several minimal cover automata of the same language that are not isomorphic. Furthermore, [6] provides an algorithm that, for a finite language L (given as an FA that accepts L or as a cover automaton of L), constructs a minimal cover automaton of the language. An improved algorithm (in terms of complexity) is also presented in [7].

This paper goes a step further by giving a procedure for constructing all minimal cover automata of a given finite

investigated and techniques for remaining given specifications

One of the strengths of using SXMs to specify a system is that it is possible to derive test sets from an SXM specification which, if satisfied, guarantee, under certain constraints, the correctness of the implementation with respect to the specification [10, 19, 20, 21]. Among these constraints are the so-called 'design for test conditions' that the SXM specification has to meet: input-completeness and output-distinguishability [10, 19]. The class of SXMs that meet these conditions is therefore of particular interest and has
